Notes On the Twobody Density Code Structure: Units and Integrations

Harald W. Grießhammer

Institute for Nuclear Studies, Department of Physics, George Washington University, Washington DC 20052, USA

Based on hgrie's and Alex Long's research of the code, these notes are expanded from my notes in hgrie's notebook [Few-N Processes With Densities, pp. 15-21]. Equation and page numbers in emphasis refer to this notebook. In addition, there are comments in the code and emails Nov 2023.

Text in texttt refers to code variable, file names, routines, etc.

1 Purpose

An explanation of the twobody code structure with emphasis on integrations and units.

2 Units

```
The "mantle" code has base unit fm (but NOT the output file/Result(), see below!):
    p12, p12p
                momenta in fm^{-1}
                 2N density in fm<sup>3</sup> (quantum numbers per volume momentum space)
    rho
                 photon omentum/energy still given in MeV
    k
   However, in finalstatesums.twobodyvia2Ndensity.f, the call
        call Calculate2BIntegralI2(...,p12*HC,P12MAG(ip12p)*HC,...)
   converts the momenta from fm<sup>-1</sup> to MeV. That subroutine is defined in calculate2BI2.f.
Therefore, that routine and the subsequent "kernel" parts of the code use base unit MeV:
    calculate2BI2.f
    2Bspinisospintrans.f part of "kernel"
                                               Therefore, the twobody "kernel diagrams"
                              part of "kernel"
    spintricks.f
                              part of "kernel"
    spintricksasy.f
in these files are all using base unit of MeV.
```

Output units: The code is constructed such that if the kernel is given in units of MeV^{-n} , then the variable Result() and its output-to-file is in $MeV^{(3-n)}$.

Multiplying by powers of HC = 197.... MeVfm translates into output of final MEs Result() into powers of fm.

EXAMPLE: Compton has twobody kernel in MeV^{-4} (n=4), so the resultant ME is in MeV^{-1} . To convert to fm, multiply by HC. In Compton, that multiplication by HC is not done in the fortran code, but later in the mathematica processing files.

EXAMPLE: Pion Photoproduction kernel has units MeV^{-2} if the output should be the twobody functions F_{TL} . Therefore, n = -2 and the Results() output is in MeV^{1} . But the F_{TL} output should be in fm^{-1} , so divide here in kernel by HC to get fm^{-1} units in Results().

Routines which compute vectors, like calcmomenta.f, simply use the same base unit in and out, i.e. are "unit neutral".

Therefore, the overall units of the output are MeV^{3-n} for a kernel with base units MeV^{-n} !

The conversion $\frac{(HC)^3}{(2\pi)^3}$ above is programmed in finalstatesums.twobodyvia2Ndensity.f's "f=...") and converts between the fm units of the "mantle" and the MeV units of the "kernel".

It ALSO includes ONE of the Fourier volumes $\frac{1}{(2\pi)^3}$ as a factor of the twobody integration. There is no second Fourier volume (killed by phase space). This guarantees that one body and twobody have the same size and can simply be summed to get the total amplitude:

$$amplitude = onebody + twobody , (2.1)$$

without any relative factors (provided both provide output in same base units). However, to include this factor or not depends on your choice of twobody kernel.

That means in pion photoproduction, one may instead define it as part of the prefactor K2n of a diagram. This implies that if you want the twobody Result() output to be F_{TL} , you must un-compensate it here by *(2*Pi)**3. On the other hand, if you want the twobody Result() output to be E_+ etc., so that you can simply add as in eq. (2.1) above, then the prefactor K2n shouldNOT contain the $\frac{1}{(2\pi)^3}$, i.e. multiply NOT with *(2*Pi)**3/HC, but with

$$K2n = sqrt(4*Pi*alpaEM)*gA*mpi**2/(16*Pi*fpi**3)*10**3$$
 (2.2)

to get Result() in the canonical units of $10^{-3}~m_{\pi+}^{-1}$.

Set your kernel up in 2Bspinisospintrans.f so that your Result() has the desired units and factors of $(2\pi)^3$. Do NOT make unit changes outside this file!

3 Integration Coding

The integral is symbolically (including the permutation factor already in the code itself, and denoting on the left the units of each line):

$$\begin{split} [\text{MeV}]^{3-n} & \begin{pmatrix} A \\ 2 \end{pmatrix} \langle M' \, | O_{12} | M \rangle \equiv \\ [\text{fm}]^{-6} & \begin{pmatrix} A \\ 2 \end{pmatrix} \sum_{\substack{\text{mt12,j12,s12,112,m12} \\ \text{in main.twobody.f}}} \sum_{\substack{\text{mt12p=mt12} \\ \text{j12p,s12p,l12p} \\ \text{in finalstatesums.*.f}}} \underbrace{\int \frac{\text{d}p'_{12} \, p'_{12}^2}{(2\pi)^3} \int \text{d}p_{12} \, p_{12}^2}_{\text{in finalstatesums.*.f}}} \\ [\text{MeVfm}]^3 & \times \text{HC}^3 & \text{in f=... of finalstatesums.*.f}} \\ [\text{fm}]^3 & \times \rho^{M'M}_{\alpha'_{12}\,\alpha_{12}}(p'_{12},p_{12};\vec{q}) & \text{in f=... of finalstatesums.*.f}} \\ [\text{fm}] & \times \sum_{\substack{\text{msp}\equiv m_{12}^{s'},\text{ms}\equiv m_{22}^{s}\\ \text{in calculate2BI2.f}}} \langle l'_{12}s'_{12}(m'_{12}-m'_{12})m'_{12}|j'_{12}m'_{12}\rangle \langle l_{12}s_{12}(m_{12}-m_{12}^{s})m^s_{12}|j_{12}m_{12}\rangle} \\ [\text{no units}] & \times \int d\hat{p}'_{12} \, d\hat{p}_{12} \, Y^{\dagger}_{l'_{12}(m'_{12}-m'_{22}^{s'})}(\hat{p}'_{12}) \, Y_{l_{12}(m_{12}-m'_{12}^{s})}(\hat{p}_{12}) \\ & \text{in calculate2BI2.f}} \\ [\text{MeV}]^{-n} & \times \underbrace{O^{\alpha'_{12}m'_{12}^{s'}\alpha_{12}m'_{12}^{s'}}_{\text{in 2Bspinisospintrans.f}}}^{\mathcal{A}} \mathcal{P}^{\dagger}_{12}; \vec{q}) . \end{split}$$

using the Clebsch-Gordan coefficients $\langle j_1 j_2 m_1 m_2 | jm \rangle$ in the convention of refs. [1, 2]. The assignation of quantum numbers between code and the quantities should be self-explaining except maybe $ms = m_{12}^s$, $msp = m_{12}^{s'}$. The isospin $t12 = t'_{12}$ is determined by the Pauli principle: $(-) = (-)^{s_{12}+l_{12}+t_{12}} = (-)^{s'_{12}+l'_{12}+t'_{12}}$, implemented in main.twobody.f for the $t12 \in \{0; 1\}$ case as t12=(1-(-1)**(112+s12+1))/2.

Only the last line is coded in the kernel's 2Bspinisospintrans.f and spintricks*.f, namely the twobody operator \mathcal{O}_{12} projected onto orbital angular momenta via Clebsches.

All other lines are coded in the mantle. The radial integration grids are set up in main.twobody.f via call TRNS(NP12A,NP12B,NP12,P12A,P12B,P12C,P12MAG,AP12MAG) The angular integration grids are set up in main.twobody.f via call Setquad12(th12,Nth12,phi12,Nphi12,...)
